

4. MANAGEMENT PROCESS

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 1

RENESAS

This video is a lecture video for the management process of security product development process.

The management process is common to all development processes: requirements management process, semiconductor product development process, and software product development process.

Now let's explain the management process.

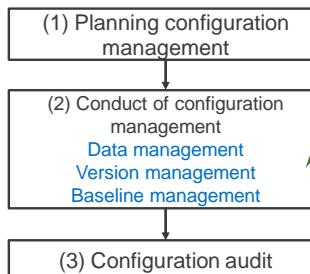

CONFIGURATION MANAGEMENT

- For security-enabled MCU/SOC products, follow RCT-JB2019-002 "6 Configuration Management Implementation Procedures".
- For software products, follow RCT-JB5001-011 "6 Configuration Management Implementation Procedures".

Management process

Purpose: To ensure that work products created in product development are maintained and managed so that the required versions of work products are correctly delivered when needed.

Configuration management type	Content
Data management	Store artifacts created in product development in a specific location so that there are no unintended changes or deletions .
Version management	Store artifacts created in product development in a specific location, record version numbers, tracked changes , and so on, so that each version of the work artifact can be taken out separately.
Baseline management	To be stored so that the work products at the time the baseline specified in the plan is met can be distinguished and taken out.

For both management, it's important to be up-to-date with work products and ensure repeatability!

First is configuration management.

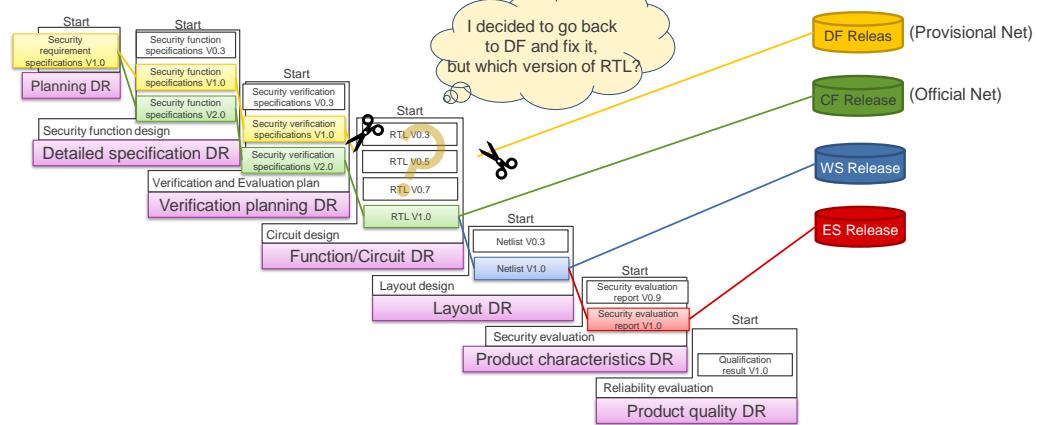

The purpose of configuration management is to ensure that the work products created are maintained and managed so that you can retrieve the correct version of the work product when you need it. In configuration management, the work products created during product development are managed using data management, version management, or baseline management. Data management is to store data in a specific location to prevent unintended changes or deletions. Version management is to record the version number and change history for each revision, and to store it in a specific location so that the work products of each version can be distinguished and retrieved. Baseline management is the management and storage of a group of work products at the time when the baseline, which is the completion reference point set in the plan, is met in a specific location so that they can be retrieved separately. The configuration management procedure is to clearly and specifically define a configuration management method at the planning stage, and during development, work products are managed at any time according to the established method, and a third party conducts a configuration audit at a specific time. The flow

is to carry out. In configuration management, regardless of the management type, it is important to be able to identify work results and ensure reproducibility.

IF YOU NEGLECT CONFIGURATION MANAGEMENT . . .

For example, if you don't manage baselines, you don't know which artifacts are tied to the release target.

For example, in release database management, if you forget to include the RTL in the baseline of a provisional net release, and you have to go back to the provisional net and make corrections, it is difficult to know which version of the RTL should be corrected. To prevent this from happening, clarify the work products included in each baseline and verify that all necessary work products are included when creating a baseline.

CHANGE MANAGEMENT

Purpose: To ensure that changes are implemented so that there is no conflict between each work product created based on requirements and requirements.

The following will be implemented.

- ✓ Analyze and review customer set and software impact
(Including impact on related fields such as functional safety.)
- ✓ Analysis and confirmation of the impact on other work products
- ✓ Whether or not to implement the change and the reason for the decision
- ✓ The result of the change and the validation result for the change result
- ✓ a plan for doing the above series of actions

- For security-enabled MCU/SOC products, follow [RCT-JB2010 "4.3 Design Change Management"](#) and [RCT-JB2019-002 "7 Procedures for Implementing Change Management"](#).
- For software products, follow [RCT-JB5001-011 "7 Procedures for Implementing Change Management"](#).

Need to keep these on record.

Next is change management.

The purpose of change management is to ensure that change requirements are implemented without creating conflicts between the requirements and the work products created based on them.

Change management:

We analyze the impact on the customer set and related hardware and software, as well as the impact on associated work products.

At this time, we also ask the people in charge of each field to analyze the impact on related fields such as functional safety.

Next, use the analysis results to decide whether or not to implement changes and clarify the reasons for that decision.

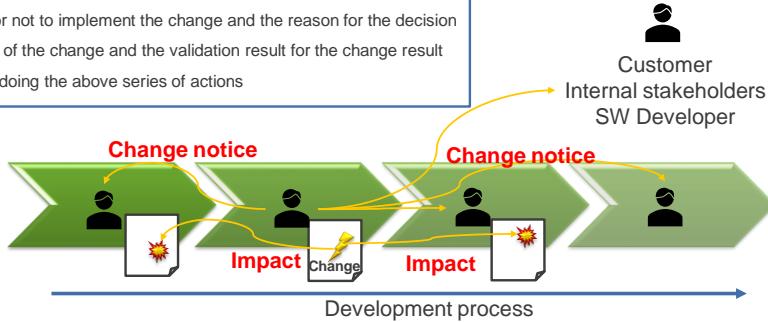

If we decide to make a change, we will implement the change and confirm the verification results of the change. In change management, it is important to keep records from change request to change completion.

IF YOU FAIL TO MANAGE CHANGES....

The following will be implemented.

- ✓ Analyze and review customer set and software impact
(Including impact on related fields such as functional safety.)
- ✓ Analysis and confirmation of the impact on other work products
- ✓ Whether or not to implement the change and the reason for the decision
- ✓ The result of the change and the validation result for the change result
- ✓ a plan for doing the above series of actions

For example, neglecting impact analysis during change management can lead to inconsistencies in specifications between each work product, and broken interfaces with customer sets and related hardware and software.

Impact analysis is one of the important matters in change management, so please use traceability information, interface information, etc. to identify the scope and details of the impact of the change request.

TRACEABILITY

- For security-enabled MCU/SOC products, follow RCT-JB2019-002 "8 Traceability Management Implementation Procedure".
- For software products, follow RCT-JB5001-011 "8 Traceability Management Implementation Procedure".

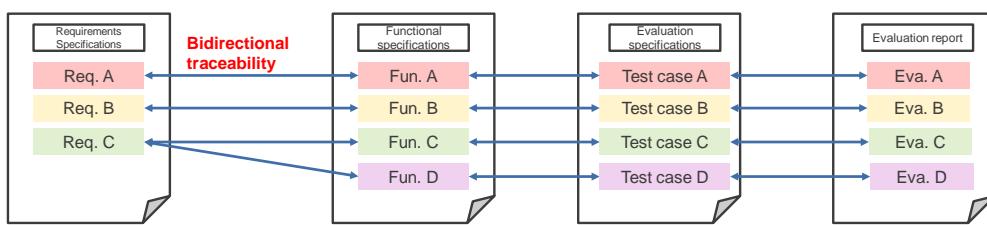

Purpose: To ensure that there are no overs or inconsistencies between each work product created based on requirements and requirements, and to ensure that the impact of changes can be identified without delay.

What is traceability management for?

All requirements, including security requirements, and each requirement and specification in the work product created based on the requirements, etc. (Quoted from RCT-JB2019-002 Chapter 8)

As a general rule, tools are used to manage traceability.

Use traceability, especially during peer review and change management.

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 6

RENESAS

Next is traceability.

The purpose of traceability is to confirm that there are no excesses, deficiencies, or inconsistencies between each work product created based on requirements, and to be able to fully identify the impact of change requests as explained earlier.

Traceability associates all requirements, including security requirements, with each requirement, each specification, evaluation items, or evaluation results, within the work products created based on the requirements. In principle, use traceability tools to implement traceability.

IF YOU'RE TRACEABILITY....

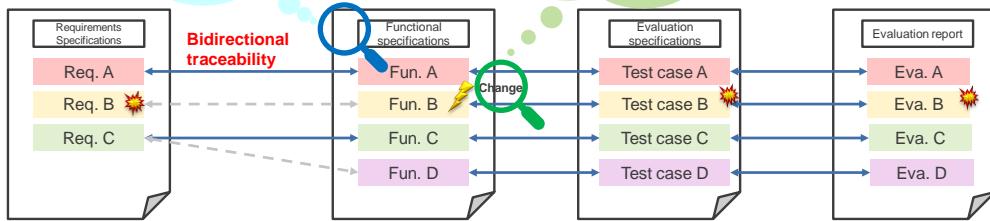

- In peer review, it can be confirmed that there is no leakage in each requirement or specification in the work product created based on requirements and requirements, and there is no contradiction in the content with the work products formulated in the upstream process.
- In change management, you can identify the impact on both upstream and downstream work products that are subject to change.

Peer review of functional specifications

- It seems that the function corresponding to requirement B has not been decided ...?
 - Function D is not required.

In change management impact analysis

- Consider whether requirement B needs to be changed.
 - Do you change the specifications of test case B?
 - Do I need to reevaluate?

For example, by ensuring traceability, you can prevent omissions in specifications, implementation, and evaluation of requirements. Additionally, as mentioned earlier in the discussion of change management, it becomes easier to identify the impact of changes.

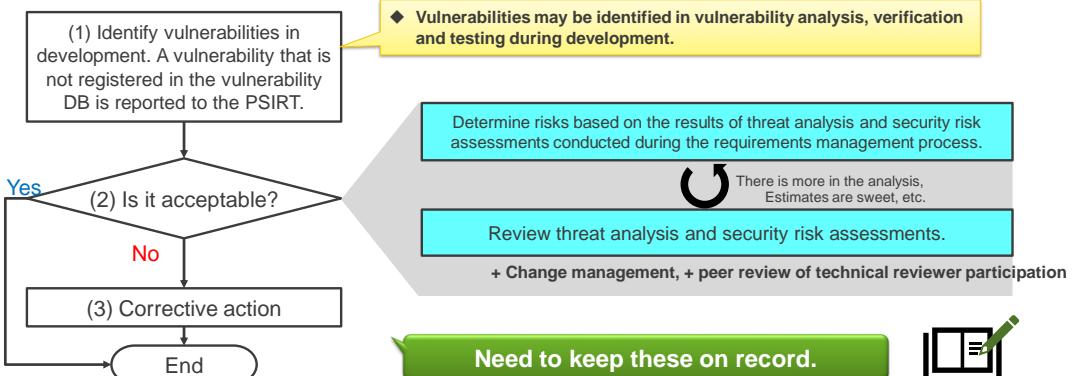

VULNERABILITY MANAGEMENT

Management process

- For security-enabled MCU/SOC products, follow RCT-JB2019 "9.3 Vulnerability Management".
- For security-enabled software products, follow RCT-JB5007 "8.2.3 Vulnerability Management".

Purpose: To determine the need for countermeasures against identified vulnerabilities to prevent unacceptable risks from remaining in the product.

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 8

RENESAS

Next is vulnerability management.

The purpose of vulnerability management is to prevent unacceptable risks from remaining in products by determining the need for countermeasures against identified vulnerabilities.

Vulnerabilities can be detected through vulnerability analysis, verification, and evaluation during development. When a vulnerability is detected, first check whether the detected vulnerability is registered in our vulnerability database.

If it is registered in the database, we will take the corrective actions listed in the database. If it is not registered in the database, please report the vulnerability information to PSIRT.

At the same time, we compare the detected vulnerabilities with the threat analysis risk assessment results conducted in the requirements management process to determine the risk level and determine whether or not it is acceptable.

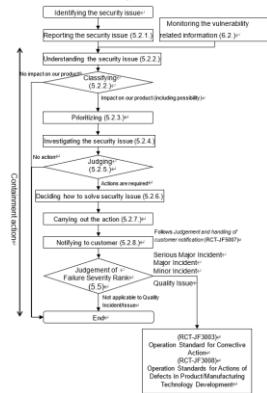

If the risk is unacceptable, develop remedial measures and take corrective actions to reduce the vulnerability below the risk tolerance. Then, we will report the corrective measures taken and the results again to PSIRT.

In vulnerability management, it is important to keep a record of everything from vulnerability detection to the end of the incident.

PROCEDURE FOR CORRECTIVE ACTION OF VULNERABILITIES

“Operation Standard for Action of the Security Incident and Vulnerabilities” (RCT-JF3009)

Role and Responsibilities of PSIRT

- ✓ Responsible for conduct containment action on security issues.
 - ✓ Determine the need to investigate reported security issues and security issues grasped through periodic monitoring, formulate or support the formulation of containment action plans, and monitor the execution of containment actions.
 - ✓ Responsible for leading continuous improvement activities for security issues.
 - ✓ Conduct periodic monitoring of external vulnerability-related information, periodic review of corrective actions for security issues, and in-house education.

**Established HPCSG-PSIRT, EPSG-PSIRT, and PSIRT for each business body,
Working in cooperation with each other.**

HPCSG PSIRT:

https://renesasgroup.sharepoint.com/sites/EI/ABUSecurity_oricess_DB/Pages/ABU-PSIRT.aspx

EPSG PSIRT:

RENESAS CONFIDENTIAL

Page 9

For detailed vulnerability handling procedures, please refer to the Operation Standard for Action of the Security Incident and Vulnerabilities, RCT-JF3009, which specifies the handling flow. Please note that our company has established HPCSG PSIRT and EPSG PSIRT for each business entity, and they operate in coordination with each other. The vulnerability database is common.

SECURITY ASSET MANAGEMENT

- Follow "Operation Standard for Security Assets Management" (RCT-JB0026).

Purpose: To maintain the confidentiality, integrity, and availability of design assets.

The following three are also called CIA taking the initials of English.

(Source : ISO/IEC 27000)

- Confidentiality:** Ensure that **only those who have access to the information have access to it.**
- Availability:** Ensure that a person who has been granted access to information has **access to information and related assets without interruption when necessary.**
- Integrity:** Ensure that **information has not been destroyed, tampered with or erased.**

How do you protect design assets and technical information?

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 10

RENESAS

Next is security asset management.

The purpose of security asset management is to maintain the confidentiality, integrity, and availability of security design assets. Confidentiality means ensuring that only those authorized to access the information have access to it.

Availability, in turn, is about ensuring that those authorized to access the information have uninterrupted access to the information and related assets when needed.

Finally, integrity means ensuring that information has not been destroyed, altered, or erased.

SECURITY ASSET MANAGEMENT PROCEDURES

(1) Formulation of plans for security asset management

(2) Conduct of security asset management
How to protect according to the security management level

- ◆ Also check the status of security asset management implementation during security audits.

(3) Audit

- ◆ Determine what to manage.
- ◆ Determine the level of security management

Security management level	Storage	Provide
1 Normal management	<ul style="list-style-type: none"> The security leader manages the security assets by the storage method specified in the security plan. The scope of sharing of security assets shall be the interested departments approved by the security leader. The storage period of security assets conforms to the "Quality Record Management Operation Standard" (RCT-JF0016). However, if there is a contract or agreement with the customer, that contract or agreement takes precedence. 	<ul style="list-style-type: none"> The provider of the security asset agrees in advance that the provider will conduct the same management as the provider. The person who provides the security assets obtains the consent of the person in charge of development in advance. The person who provides the security asset keeps a record of the destination, purpose, and deadline. Security assets that have exceeded the delivery deadline will be discarded, returned, or extended as necessary. The person who provides the security assets uses encryption to prevent the security assets from being leaked or tampered.
2 Strict management	<p>In addition to the security management level 1 provisions, implement the following.</p> <ul style="list-style-type: none"> The scope of sharing of security assets shall be individuals such as development members approved by the security leader and stakeholders (sharing of the entire department is not possible). The security leader periodically checks the usage agreement (leakage, loss, falsification, etc.) of security assets from the start of development, and then reviews the disposal or continuation of storage. 	<ul style="list-style-type: none"> In principle, it is prohibited to provide security assets outside the shared scope.

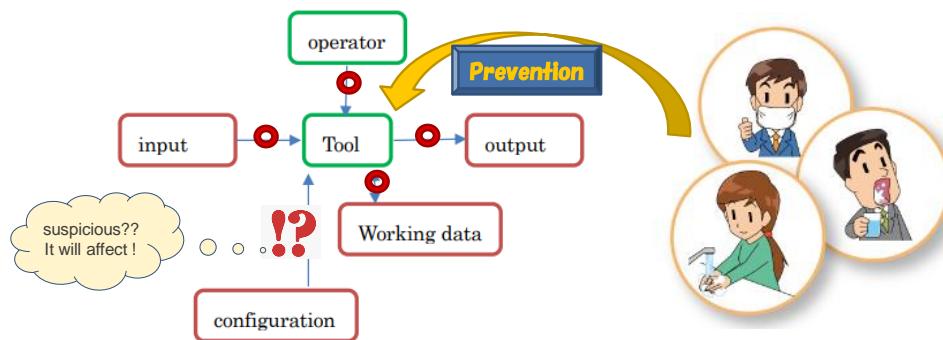

The procedure for security asset management is to create a security asset management plan during the planning stage, including deciding what to manage and building a protected environment, and during development to maintain protection of security assets based on the plan. Then, the status of security asset management will be audited by a third party at a specific time. The details of security asset management are explained in detail in the security asset management section of the security process introduction education.

SECURITY TOOL MANAGEMENT

The procedure follows "Operational Guideline for Tool Management in the development of Security Products "(TOS-DS00201)

Purpose: To identify and identify tools that affect security, then prevent that risk.

Next is security tool management.

The purpose of security tool management is to identify tools that impact the security functions you implement and prevent the risk of that impact.

Security tool management begins with investigating whether the tools you use have the potential to impact the security features you implement.

For each tool you use, consider the impact on the security functions you implement from various perspectives, including input/output, operators, operating procedures, tool configuration information, and tool work data.

PROCEDURE FOR SECURITY TOOL MANAGEMENT

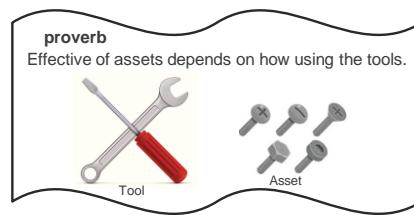

① Identify tools that affect security

No.	Tool general information				Purpose	Impact Analysis	
	Tool name	Tool vendor	Tool version	From central list		Security Impact	Rationale

② Analysis of predefined threats, scopes and mitigations

Threat section			Mitigation section		
Threat	Scope	Impact	Rationale	Mitigation	Status and Evidence(Link)

③ Conduct mitigation measures and leave implementation status and evidence

④ Using the tool

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 13

RENESAS

We will explain the security tool management procedure.

Using the form attached to TOS-DS00201, the technical standard for security tool management, identify whether or not the tool will affect the security functions to be implemented before using the tool.

Examples of tools include:

- Tools used for concept and product development, such as compilers, static checkers, and verification tools.
- Tools used during device evaluation such as debuggers.
- Tools used during device manufacturing such as flash programmers and testers. Etc.

Next, if it is determined that there will be an impact, we will analyze the degree and scope of the impact, formulate and record the analysis results and mitigation measures to minimize the impact.

Then, implement the developed mitigation measures and remove the risk of impact on security functions.

At this time, be sure to keep a record of the implementation or the application of the mitigation measures.

By doing this, you will be able to use security tools during development.

This concludes the explanation of the management process.

SUMMARY OF MANAGEMENT PROCESSES

Conduct basic configuration management, change management, and traceability management correctly, and then vulnerability management, security asset management and tool management.

Do it properly in the event of a change or failure.

RENESAS

Summary of management processes.

After properly implementing basic configuration management, change management, and traceability management, we perform vulnerability management, security asset management, and security tool management.

It is important to keep accurate records of any management process.

Next, we will move on to an explanation of customer contracts and supplier selection.

5. CONTRACT WITH CUSTOMER / SUPPLIER SELECTION

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 15

RENESAS

5. Contract with customer, and supplier selection.

CIA/CIR

Contract with customer

Sec

- The procedure follows "ISO 21434 Operational Guideline for Cybersecurity Interface Agreements and Reports" (TOS-DS00189).

Purpose: Clarify the division of responsibility for ISO 21434 requirements between product recipients (customers) and product suppliers (suppliers).

- ✓ When developing a product that complies with ISO 21434, the CIA / CIR are
 - A document that clearly indicates to the product the customer and our security responsibilities.
 - A document that clearly indicates the scope of responsibility for the security of the purchaser or contractor and our company for the purchased parts or outsourcing.

■ CIA : Cybersecurity Interface Agreement

A contract document that agrees on the division of responsibilities between the product recipient and RENESAS for the requirements of ISO 21434, and the necessity of submitting security work products. Handle in accordance with the "Basic rules for contract management" (RER-CB03).

■ CIR : Cybersecurity Interface Report

A document that unilaterally notifies the product recipient of the scope of responsibility of RENESAS (not an agreement, not treated as a contract document).

**Avoid the risk of development rework due to disagreement in the division of responsibilities and troubles after mass production.
Determine our security activities required by the product.**

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 16

RENESAS

First, there is the contract with the customer.
We refer to contracts with customers for products that comply with ISO 21434 as CIA and C I R.
CIA and CIR apply only to automotive security products.
The purpose of CIA and CIR is to clarify the division of responsibility for ISO 21434 requirements between customers and suppliers. CIA and CIR are documents that clarify the scope of responsibility for security implemented in products, and are applicable to customers selling products, purchasing suppliers, and subcontractors. In other words, please understand that CIA and CIR are the security versions of DIA and DIR for functional safety for automobiles. The handling of CIA and CIR is stipulated in detail in the technical operation specification, TOS-DS00189, and the respective forms are also in place.

Contract with customer

CIA / CIR FORMS (EXCERPT) (TOS-DS00189)

Renesas product CIA

This CIA is used to indicate development interface between Renesas and the customer according to ISO/SAE 21434-2021.

The scope of this CIA is security lifecycle for a product shown in a cover sheet of this document.
The customer is responsible for checking validity of Renesas product's assumption of use on the customer's system.
Each work product shown below and related requirements are interpreted as ones for Renesas product development.

Legend:

R	Responsible and accountable
S	Applicable if any support (e.g. support, inform, consult) to the customer is provided in the target product's security lifecycle. Provided support is clearly defined in "Comment" column if applicable.
X	Applicable
O	Out of scope
(X)	It is in scope of the product security lifecycle but its applicability depends on the product strategy. The applicability is decided before submission of CIA/CIR to the customer.
-	Not applicable
Out	Out of the target product's security lifecycle
S>>C	Applicable if any security related deliverable is provided from the supplier to the customer

Caution:

- This template is not approved by Legal div. Please get approval from legal div.

- according to defined process before signing this DIA.

- Green-colored cells are for internal use. Please delete all the cells before

- submission to the customer.

- This template assumes to be used for a low level driver (e.g. MCAL). Contents of the template need to be modified to fit this DIA contents to safety lifecycle of the target product.

- The DIR template is just providing a framework of DIR. The basement of the

- contents must follow the latest DIA template.

RENESAS responsibility

R : Responsible (execution / explanation)

S : Support (content describes in the comment section)

From the left side, the format is the work products defined in ISO 21434, the person responsible for those work products, and the name of the deliverable. CIA agrees and enters into a contract with the customer, supplier, or subcontractor regarding who is responsible for each work product. On the other hand, the CIR only informs the customer of who is responsible for each work product. A CIR is a notification and not an agreement, so it does not constitute a contract.

SELECTION OF DESIGN OUTSOURCING

Supplier selection

- The procedure follows "Operation Standard for Quality Control of Design Consignment" (RCT-JB0016).
- In the case of IP purchase, follows the "Implementation Standard for IP (Design Asset) Purchase" (RCT-JB1004-002).

Purpose: Confirm the availability of security measures and select an outsourcer for design work.

- ◆ When designing and outsourcing part or all of security product development to non-affiliated companies in Japan and overseas, use RCT-JB0016 Form 1 "Quality Requirements Confirmation Form" to confirm the security maintenance status of the outsourced candidate.
- ◆ If there is an item that requires improvement in the result of checking the security maintenance status, perform the ordering procedure including the measures for the improvement item.

Quality control requirements		Document No.			
		Issue date	(Month day, year)		
Category	No.	Requirement	Answer	Document	Remarks
		Description	Yes	No	
Security	11	(Applicable only for cyber security compatible development) Do you take information security measures such as access control and leakage prevention for non-related persons such as design input items provided by us and your company's deliverables?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
	12	(Applicable only for cyber security compatible development) Is your company has a development procedure that complies with international cybersecurity standards (all or part of it), is it possible to disclose that procedure? Or is our cybersecurity-relevant development procedure applicable?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
	13	(Applicable only for cyber security compatible development) If a security incident occurs, is it possible to take corrective action such as investigating the cause, estimating the risk, and taking measures?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 18

The next step is to select a design subcontractor. The purpose of selecting a design subcontractor for security product development is to confirm the ability of the subcontractor to implement the security requirements that we require of the subcontractor, and to select an appropriate subcontractor for the design work.

When outsourcing some or all of our security product development, please use Form 1 of RCT-JB0016 and the Quality Requirements Confirmation Form to confirm the security capabilities and maintenance status of the potential subcontractor.

Based on the confirmation results, please select a subcontractor that can meet our security requirements. If there are any items in the survey results that require improvement at the selected subcontractor, please complete the purchasing specifications and outsourcing contract, including the measures for improvement.

6. SUMMARY

© 2024 Renesas Electronics Corporation. All rights reserved.

RENESAS CONFIDENTIAL

Page 19

RENESAS

Finally, a summary.

SUMMARY

- Security product development consists of **regular development and security development work**. Make sure that the results of regular development and the results of security development work **do not deviate from each other**.
- Develop with an **awareness of the purpose** of each security development work.
- It is necessary to conduct the management process not only during development **but also after the development is completed**.

First, security product development consists of a combination of regular development and security development. It is important to promote development so that the results of regular development and security development do not diverge.

Second, please be aware of the purpose of each security development when proceeding with development.

Third, management processes need to be implemented not only during development, but also after development is complete.

With this, we conclude the security product development process of the Renesas security process introduction. Thank you for listening.
